Although *E. coli* is primarily a commensal of mammals, and to a lesser extent birds, it can be isolated from a variety of host species as well as soil, sediments, and water. It has long been recognized that *E. coli* exhibits quite extensive substructuring and that the relative abundance of the most common phylo-groups varies with respect to host age and sex, host species, as well as geographical location. Strains belonging to some phylo-groups are much more frequently encountered in water samples than strains belonging to other phylo-groups. The extent to which strain survival in the external environment has determined the evolutionary origins of the various diarrheal pathotypes is unknown. There is a growing body of evidence that indicates commensal *E. coli*, like the diarrheal pathotypes, exhibits at some tissue specificity within the gastrointestinal tract. However, there is little evidence to suggest that commensal *E. coli* exhibit extensive host specificity as is the case with many of the diarrheal pathotypes.
